Ice Apocalypse
Rapid collapse of Antarctic glaciers could flood coastal cities by the end of this century.

By Eric Holthaus on Nov 21, 2017

In a remote region of Antarctica known as Pine Island Bay, 2,500 miles from the tip of South America, two glaciers hold human civilization hostage.

Stretching across a frozen plain more than 150 miles long, these glaciers, named Pine Island and Thwaites, have marched steadily for millennia toward the Amundsen Sea, part of the vast Southern Ocean. Further inland, the glaciers widen into a two-mile-thick reserve of ice covering an area the size of Texas.

There’s no doubt this ice will melt as the world warms. The vital question is when.

The glaciers of Pine Island Bay are two of the largest and fastest-melting in Antarctica. (A Rolling Stone feature earlier this year dubbed Thwaites “The Doomsday Glacier.”) Together, they act as a plug holding back enough ice to pour 11 feet of sea-level rise into the world’s oceans — an amount that would submerge every coastal city on the planet. For that reason, finding out how fast these glaciers will collapse is one of the most important scientific questions in the world today.

To figure that out, scientists have been looking back to the end of the last ice age, about 11,000 years ago, when global temperatures stood at roughly their current levels. The bad news? There’s growing evidence that the Pine Island Bay glaciers collapsed rapidly back then, flooding the world’s coastlines — partially the result of something called “marine ice-cliff instability.”
How do we project changes in global sea level?

Figure 15: PISM’s view of interfaces between an ice sheet and the outside world.
Challenge 1: Ice sheet models are under-constrained

Challenge 1: Ice sheet models are under-constrained

DeConto and Pollard (2016), *Nature*
Constraining ice sheet model parameterisations

- Use PISM to simulate the past evolution of the Antarctic Ice Sheet.
- Run the model many times. Perturb the model physics each time, sampling as many different parameter combinations as possible.
- Identify the model configurations where the simulated evolution of the ice sheet agrees best with the known history.

Challenge 2: Boundary conditions

Present Past

Steven J. Phipps, IMAS, UTAS
Antarctica and global sea level
AORI, UTokyo, 28 Nov 2017
Using climate modelling to generate boundary conditions

- Using the CSIRO Mk3L climate system model to simulate:
  - 26–0 ka, then 5,000 years into the future
  - 70–0 ka, then 5,000 years into the future
  - 120–0 ka, then 5,000 years into the future

- Next step: data assimilation
Using climate modelling to generate boundary conditions

- Surface air temperature anomaly (°C)
- Precipitation anomaly (%)
- Surface air temperature (°C)
- Annual precipitation (mm)
Challenge 3: Evaluating ice sheet model simulations
The history of the Antarctic ice sheet (60–0 ka)

Antarctica and global sea level

AORI, UTokyo, 28 Nov 2017 17 / 18
Potential areas for collaboration

- Constraining ice sheet model parameterisations
  - Improving representations of known physical processes
  - Incorporation of hypothetical physical processes

- Simulating past and future changes in the atmosphere and ocean
  - Ensemble simulations using coupled atmosphere–sea ice–ocean general circulation models
  - Assimilation of Southern Hemisphere proxy data
  - Ice sheet–ocean coupling?

- Reconstructing past changes in the Antarctic ice sheet
  - Reconstructing past changes in ice thickness and extent
  - Using reconstructions to evaluate ice sheet model simulations
